Design and Construction of Embankment Dams

Embankment Dams Design and Construction Identifying needs Embankment dams are commonly the lowest cost alternative type to construct because they can utilise locally available earth and rock fill materials and can be built on lower quality foundations than other dam types. Embankment dams are the most prevalent worldwide,

design work to be undertaken. The aim of such a survey is to present, on paper, a contour map of the reservoir up to and exceeding the maximum flood level, and to provide details for the location of the embankment, spillway and outlet works. From the contour map, the capacity of the reservoir can be assessed for varying dam heights.

The modern dam Basic problems in dam design. Most modern dams are of two basic types: masonry (concrete) gravity designs and embankment (earthfill or rockfill) designs. Masonry dams are typically used to block streams running through relatively narrow gorges, as in mountainous terrain; although the structures may be very high, the total amount of material required for such sites is limited.

Types. Embankment dams come in two types: the earth-filled dam (also called an earthen dam or terrain dam) made of compacted earth, and the rock-filled dam. A cross-section of an embankment dam shows a shape like a bank, or hill. Most have a central section or core composed of an impermeable material to stop water from seeping through the dam.
